10-MINUTE VIDEO PRESENTATION

CLYORA

AI-assisted employee onboarding,
from fragmented handoffs to one governed journey.

PRESENTER SCRIPT	5-SLIDE STORY	LIVE DEMO CUES

Built for the university challenge recording: one clear user problem, a real end-to-end workflow, the AI harness, safety and evidence, then honest next steps.

Timing includes short screen transitions. Read at a conversational pace; text in the blue cue panels is an instruction for the presenter, not narration.

START HERE

The brief, translated into a 10-minute story

The supplied challenge brief asks for a useful AI product feature inside a governed engineering harness. It explicitly requires a 10-minute recording and a five-slide story.

Run of show

TIME	SLIDE	WHAT THE REVIEWER SHOULD SEE
00:00-01:10	**1. Problem and value**	Who is stuck, why the handoffs matter, and what CLYORA changes.
01:10-04:20	**2. Product workflow and demo**	HR creates and approves a plan; employee and manager do their work; payroll has an explicit review gate.
04:20-06:15	**3. Architecture and harness**	How trusted context, model proposals, deterministic checks and persistence fit together.
06:15-08:20	**4. Safety and evidence**	Security boundaries, human decisions, validation, testing evidence and known limits.
08:20-10:00	**5. Impact and next steps**	Expected value, how it will be measured and what must be connected next.

Challenge scoring to cover

CATEGORY	WEIGHT	EVIDENCE TO SAY OR SHOW
Product value	**25%**	A concrete onboarding problem and a coherent workflow.
Harness engineering	**25%**	Contracts, validation, guardrails, fallback and human oversight.
LLM implementation	**20%**	Grounding, retrieval, citation integrity and useful refusal behavior.
Engineering quality	**15%**	API/data design, checks, observability and clear documentation.
Demo recording	**15%**	A legible end-to-end walkthrough with technical explanation.

> Recording rule: do not invent an ROI number, model accuracy score, or production integration. The script names expected impact and separates it from measured results.

SLIDE 1 | 00:00-01:10 TARGET TIME

Problem and user value

Slide goal: make the coordination problem understandable before naming implementation details.

ON SCREEN: Open on the CLYORA workspace or a clean title slide. Keep the screen uncluttered; point to HR, manager, IT, payroll, benefits, training and employee as the handoff chain.

SAY

Hello, and thank you. We are presenting CLYORA, an AI-assisted employee onboarding orchestrator. The problem is coordination: a new hire depends on HR for records, a manager for team readiness, IT for equipment and access, and payroll, benefits, and training for service-specific steps. Those handoffs often sit in separate checklists and messages. A missed owner or prerequisite can make a new employee wait on day one.

CLYORA gives the journey one plan with an owner, due date, dependency, and status for each task. HR gets organization-wide readiness; the manager sees team actions; the employee sees personal work and progress. The goal is fewer missed handoffs and a clearer first day. We have not measured that improvement yet, so I will show the workflow and the controls instead of claiming a savings number.

Our design follows the challenge's employee onboarding use case: coordinate work from the employee's profile and location, while keeping important decisions with people. I will walk through one prepared example and show where AI helps, and where it must stop.

SLIDE CONTENT: One new hire, several teams, one accountable journey. Value proposition: clearer ownership, fewer missed handoffs, visible day-one readiness.

SLIDE 2 | 01:10-04:20 TARGET TIME

Product workflow and live demo

Slide goal: show the same employee journey from HR, employee, manager and payroll-review perspectives.

DEMO ORDER: HR employee record -> generated plan and findings -> HR plan approval -> employee service work -> manager tasks -> payroll HR verification -> final HR sign-off -> audit. Use a prepared example; do not type real personal or bank details.

SAY

I will start in the HR workspace. We create or open a prepared new-hire record and confirm the department, role, location, start date, and manager. Location matters because some obligations and deadlines depend on jurisdiction. From this profile, HR asks CLYORA to prepare an onboarding plan.

The plan is a proposal, not an automatic instruction. The model can help select and organize work, while templates and deterministic rules preserve the required task types, owners, services, dates, and prerequisites. I can review the task list, policy citations, validation findings, and dependencies. Tasks with legal or pay impact are marked for review. HR acknowledges the plan and approves it before downstream work is dispatched. That approval is the first human control point.

Next I switch to the employee workspace. The employee sees their own journey and can follow what is due, blocked, or complete. The service screens guide document submission, equipment receipt, benefits, training, and payroll setup instead of asking the employee to find instructions in email. For payroll, the employee enters pay frequency, currency, tax form type, and bank details in the protected form. I use example values only. The API does not retain the full bank number; it retains only the last four digits for verification.

The employee cannot verify their own payroll setup. I switch back to the authorized HR administrator, review the submitted setup, and explicitly confirm it. Once verified, the payroll fields are locked. This keeps employee input separate from approval and leaves an audit trail.

In the manager workspace, we see the manager-owned actions: assign a buddy, prepare the first-day agenda, review requested access, schedule introductions, and set probation goals. The work queue shows one employee's latest active plan at a time, so an older plan does not flood the view with duplicate tasks. After all required work is complete or explicitly skipped, HR reviews the completed journey and records final sign-off. Only then does the plan become complete and the employee become active. I finish on the status and audit history, which show who owned the work and how the journey reached that decision.

LIVE DEMO SAFETY: Use synthetic or redacted records on screen. Avoid showing personal email, identity documents, passwords, bank account numbers, OIDC secrets, or admin credentials.

SLIDE 3 | 04:20-06:15 TARGET TIME

Architecture and AI harness

Slide goal: explain why the system is more than a prompt wrapped around a database.

ON SCREEN: Show this sequence, then open the plan findings/dependency view or a simple architecture slide.

SAY

The frontend is React and TypeScript. It calls a TypeScript API with shared, typed contracts; the backend uses Express, Prisma, and PostgreSQL. Zod schemas validate requests and generated proposals, and the API contract is published as OpenAPI.

For a plan, the system processes the worker profile, retrieves approved policy clauses and templates, and may ask the configured model for a structured proposal. The proposal passes an eight-part validation chain: schema shape, citation integrity, jurisdiction scope, mandatory coverage, dependency graph integrity, recomputed deadlines, authority guards, and a closed task vocabulary. The task generator merges authoritative rules, checks the dependency graph for cycles, calculates task ordering and critical path, and saves findings with the plan.

The provider adapter supports configured Ollama or Gemini use, with a deterministic operational baseline when model generation is unavailable. The baseline is not a substitute for legal policy: jurisdiction-specific legal, payroll, and compliance tasks must come from approved stored sources. The model can suggest; the server validates; HR approves; service workflows record the work.

SLIDE 4 | 06:15-08:20 TARGET TIME

Safety, testing and evaluation evidence

Slide goal: show concrete controls, report verification accurately, and name what remains unverified.

ON SCREEN: Show plan findings/citations, a pending approval gate, payroll review state, or the audit history. Do not expose secrets or employee private data.

SAY

The challenge asks us to make AI output safe, traceable, testable, and subject to human oversight. CLYORA grounds plan tasks in stored policy clauses. A citation must point to a real clause and quote its text. Jurisdiction mismatch, missing mandatory coverage, invalid task types, unsafe authority, or a cyclic dependency can be rejected or flagged instead of silently accepted. The plan records validation findings so a reviewer can see what was repaired, inserted, or refused.

Identity and permission are separate from model output. Keycloak handles organization sign-in. Application roles and data scopes come from the database: HR can work across the organization, a manager is limited to their reports, and an employee is limited to their own record. The model cannot assign roles or grant access. Sensitive service actions use separate permission checks. Payroll is employee-submitted, HR-verified, and audited; the full bank number is not retained.

The project verification notes record a local suite of 16 logic and artifact tests and selected database integration checks for sign-in, plan generation, dependencies, approvals, and document boundaries. For this preparation, the production build and lint checks also pass. We are not claiming that every role and screen has exhaustive end-to-end coverage: the project notes identify gaps. Live model inference and public Docker deployment were not verified, and supplied policy examples still need organization review before real compliance use.

We also have not measured onboarding time saved or a model accuracy score. Instead, the system exposes reviewable signals: citations, validation findings, task state, and audit history. That is the evidence we can responsibly show today.

EVIDENCE TO SHOW: one valid citation, one dependency, one human approval state, one role-limited screen, and a persisted audit event. Do not present a test count as a current run unless you rerun that suite.

SLIDE 5 | 08:20-10:00 TARGET TIME

Expected impact and next steps

Slide goal: finish with measurable outcomes and a credible path from prototype to deployment.

> ON SCREEN: Return to the plan progress summary, then show a short impact/roadmap slide. Leave 10 seconds for the close.

SAY

The expected business impact is a more predictable start for each employee: fewer missed handoffs, earlier visibility of blockers, and clearer accountability across HR, managers, IT, and the employee. Those outcomes are hypotheses until measured. In a pilot, I would track time from employee creation to approved plan, tasks completed by the start date, overdue and blocked tasks, corrections made by HR, and employee and manager feedback. We should compare against a baseline before claiming improvement.

The next steps are practical. First, replace demonstration policy material with reviewed company policies for each supported jurisdiction and build a repeatable evaluation set for grounded plans and refusals. Second, add verified email notifications and connect real HRIS, identity, equipment, and payroll providers where the organization is ready. Third, move background jobs and documents to durable production infrastructure, then expand role-by-role end-to-end security testing and deployment verification.

CLYORA's central design principle is simple: AI helps coordinate work, deterministic controls constrain it, and people remain accountable for important decisions. That gives us a useful prototype and a clear way to improve it safely. Thank you.

Close on screen

> AI coordinates. Rules constrain. People decide.
> End the recording at 10:00; do not add an unplanned second demo.

APPENDIX / RECORDING PREP

Demo runbook and accurate claims

Use this page while preparing the browser and recording. It is intentionally operational rather than part of the spoken script.

Before you press Record

- Confirm PostgreSQL is reachable, the API authenticates, and the frontend targets the intended API.
- Start Keycloak and verify the pre-provisioned HR, manager, and employee users. Keep each role in a separate browser profile.
- Prepare one synthetic employee with an active plan and payroll task, plus a completed example for final HR sign-off.
- Use a saved plan if live inference may be slow. Explain that model proposals are validated and a deterministic baseline is available.
- Use synthetic data only. Keep emails, passwords, OIDC secrets, identity documents, and bank numbers out of view; set readable zoom and close unrelated tabs.
- Check timing at 4:20, 6:15, and 8:20. If behind, shorten transitions, not the safety and limitations section.

Claims to keep precise

TOPIC	SAFE WORDING
AI and orchestration	Say that the model proposes structured tasks. Rules, stored templates, the validator chain, and HR approval govern what is saved and dispatched.
Policy assistant	It searches approved stored sources and cites them. It is not a general HR authority and should refuse unsupported questions.
Payroll	This prototype captures onboarding payroll details and approval state. It is not connected to a payroll processor; only the last four bank digits are retained.
Email and provisioning	Employee activation depends on Keycloak admin-client and SMTP configuration. Do not claim successful delivery unless you tested it in this environment.
Impact	Describe expected benefits and proposed measures. No business outcome or accuracy percentage has been measured.
Deployment	The repository documents a container path, but public deployment and Docker runtime were not verified in the project notes.

Local run reminder

With .env configured and the database online, run npm run auth:up if needed, then npm run dev:api and npm run dev:web in separate terminals. Open http://localhost:5173. For Neon, confirm both database URLs point to the active project.
